1. Introduction

This supplementary material provides additional visual examples for our project report Point-Set Alignment Using Weak Labels.

1.1. Methods

In Figure 1 we depict the main problem our project tries to solve. Aligning a well estimated head point cloud to a human shaped point cloud is already solved by probabilistic based rigid registration methods like FilterReg [1]. However, aligning a badly estimated head point cloud to a human shaped point cloud becomes challenging.

1.2. Data

In Figure 2 we show an entire point cloud of our test dataset with the estimated SMPL [2] mesh model for each person. The head of the SMPL mesh model of the left person is estimated quite good, whereas the head of the right person's mesh model is estimated badly. The resulting point clouds are seen in Figure 1. In Figure 4 we depict the head segment of the estimated SMPL [2] model. We crop the point cloud according to a bounding box (denoted in white) around the estimated head. The better a SMPL mesh model is estimated, the smaller the bounding box can be chosen. This would improve transformations, however, if a mesh model is estimated badly, a small bounding box could crop out the points of the target's head. A sequence of these crops is shown in Figure 3.

1.3. Evaluation

In Figure 5 and Figure 6 we show example results of the DCP registration on different datasets (please note the examples may not be representative for the performance overall and are picked for illustrative purpose). In Figure 7 we show how we evaluate our methods using 2D face bounding boxes as ground truth for quantitative evaluation. The detections, denoted by the red boxes, are generated by drawing a rectangle around the rendered mesh.

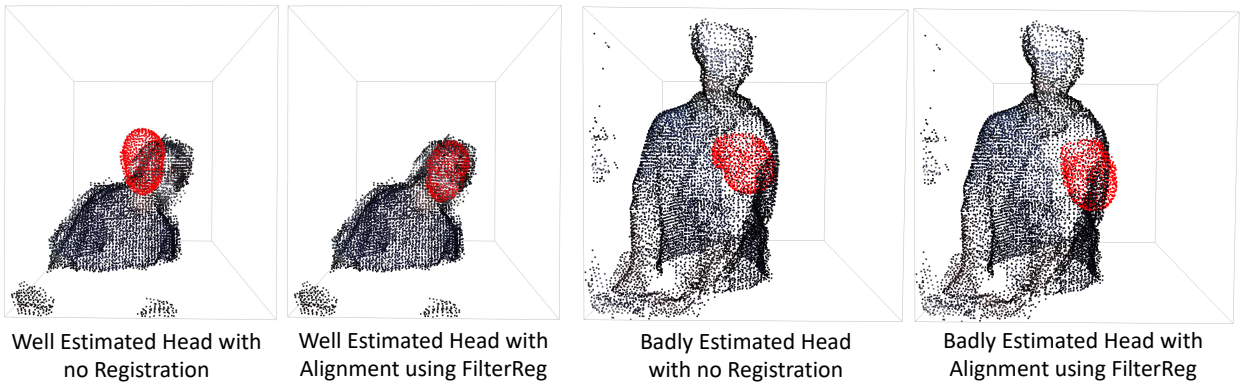

Figure 1. Illustration of the main problem we try to solve. The left side shows an already well estimated head point cloud (red) and a target point cloud (human shaped). Probabilistic based methods like FilterReg [1] perform well on well estimated heads. The right side shows a badly estimated head. Using FilterReg results in an inadequate alignment.

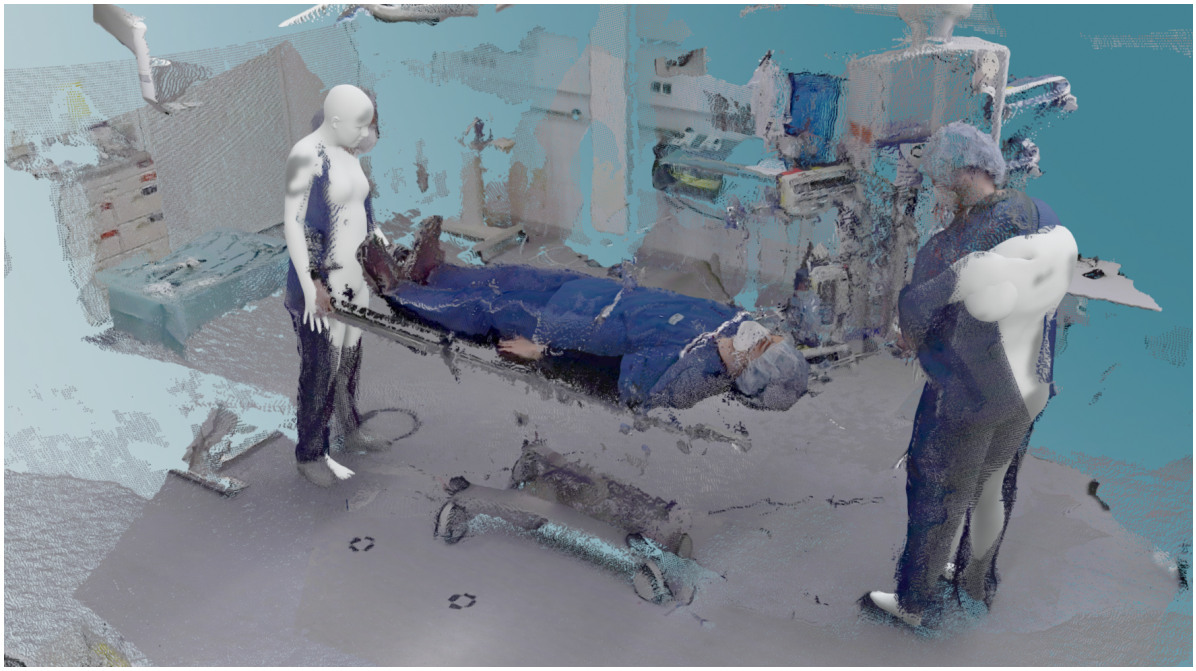

Figure 2. Point cloud of the entire OR scene from our test dataset with estimated SMPL [2] models. Note that the head of the left mesh is aligned quite well while the head of the right mesh is estimated poorly.

Figure 3. Sequence of three frames of imperfect real-world data in which the operator slightly turns

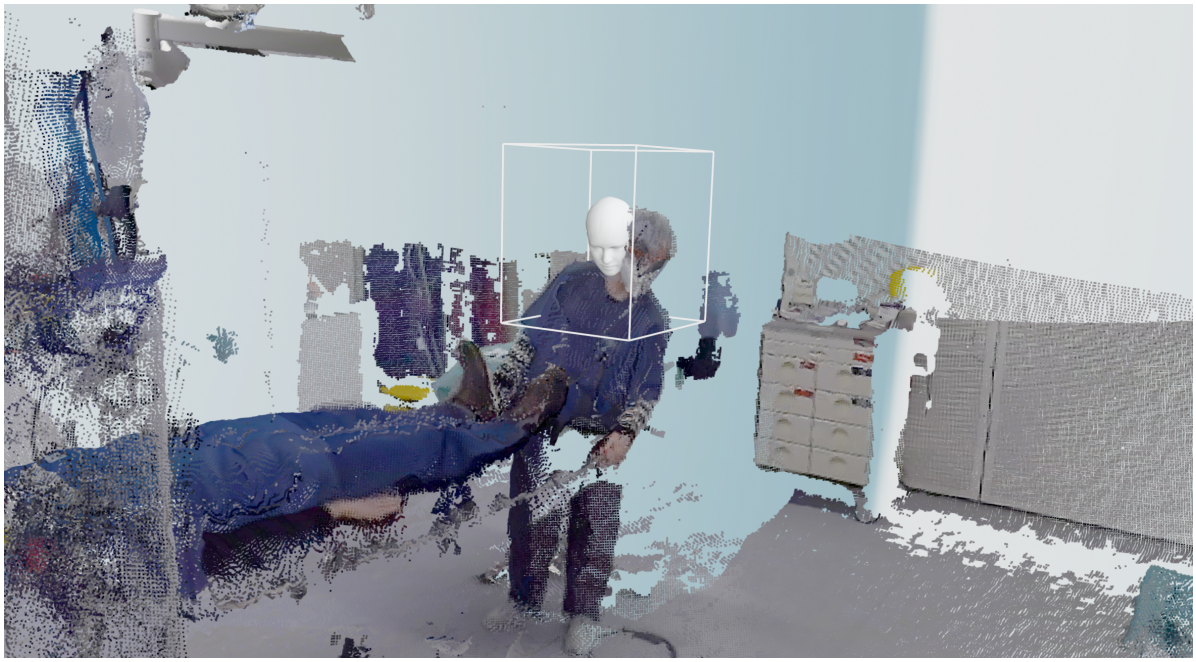

Figure 4. 3D illustration of the extracted head segment of the SMPL [2] mesh and the corresponding bounding box where the point cloud is cropped.

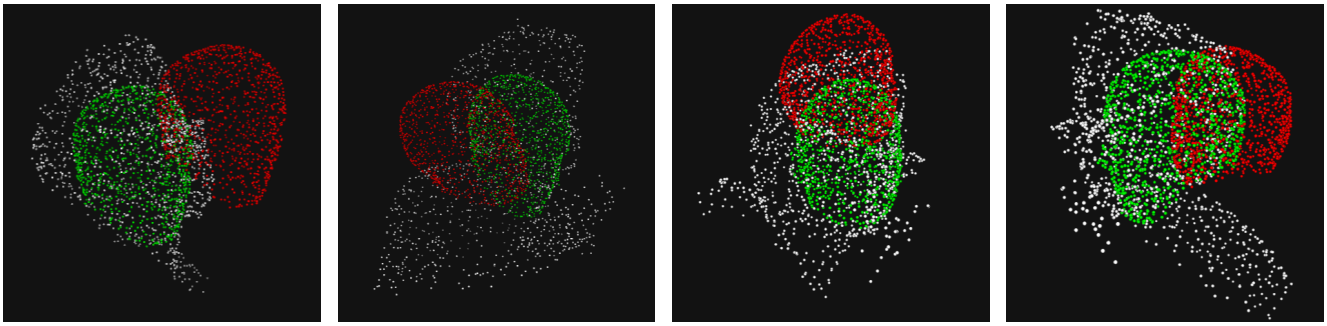

Figure 5. Examples of predictions on our synthetic data. The bounding box of the cropping is set to $[0.1, 0.1, 0.1]$. Here, the red point cloud denotes the misaligned head and green the prediction.

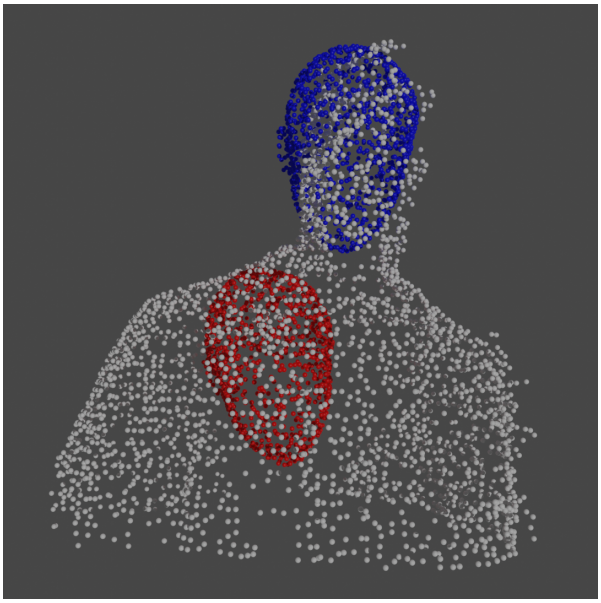
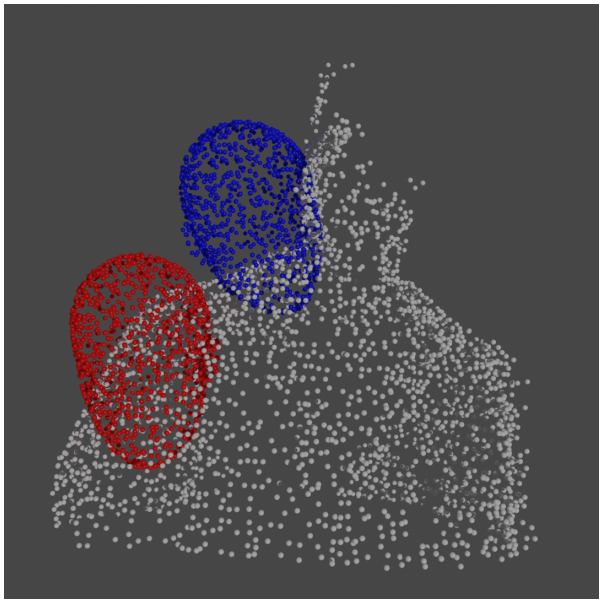


(a) Example of real-world data with a highly accurate alignment



(b) Example of real-world data with an inaccurate alignment

Figure 6. Two examples of the synth. DCP-v2 model on our test data. The red point cloud is the (badly) estimated head of the SMPL [2] mesh and the blue point cloud is the prediction.

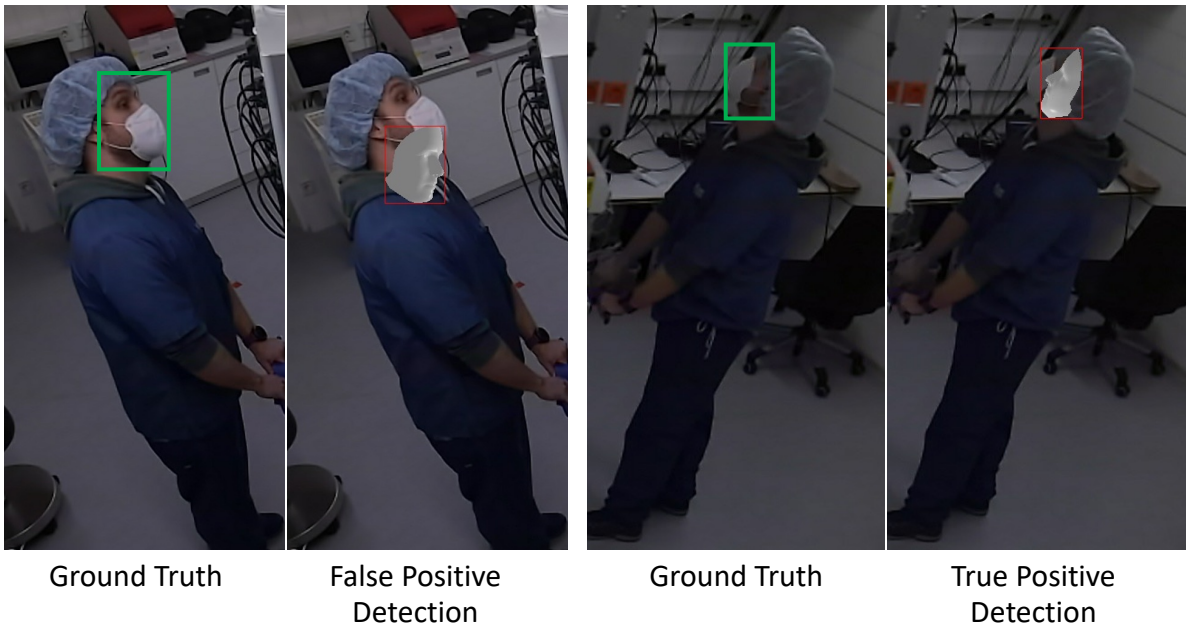


Figure 7. Example of rendering the mesh back into the 2D images for our quantitative evaluation. The green boxes denote the ground truth face bounding box annotation, whereas the red boxes denote the our detection.
